Download: inpa.ediabas.rar) Genetically engineered human and mouse monoclonal antibodies for cancer therapy. Monoclonal antibodies (mAb) represent a promising class of therapeutics for the treatment of cancer. One of the first mAb-based cancer therapeutics to enter clinical trials is the humanized anti-CD20 antibody Rituximab. Since then, monoclonal antibodies have been shown to have high affinity, specificity, and a prolonged half-life compared with other classes of biologics. Many antibody formats have been shown to be efficacious in preclinical models of disease, suggesting that there is a range of possibilities for the development of antibody-based cancer therapeutics. This review examines the genetically engineered antibody variants that are being developed for cancer therapy, including in vitro selection methods, the use of humanized antibody gene libraries, and the use of extracellular domain knockouts.

Q: Single Table Inheritance through polymorphism? Using the example of this question I am running into an issue with building a polymorphic (is it a good term?) model. I have two tables in my database: Team (Team_id, Team_name, Team_logo) (pk: team_id) and Group (Team_id (FK), Group_id (PK)). What I want to do is with all new entries of Team, create a Group entry for that team, and then add the logo to that group. This seems like a perfect candidate for Single Table Inheritance, right? My original idea was to have an abstract class Team that subclasses Team and Group:

```
public abstract class Team {
    public int Team_id {get;set;}
    public string Team_name {get;set;}
    public abstract int Group_id {get; set;}
    public virtual Group Group {get; set;}
}
public class TeamA : Team {
    public int TeamA_id {get; set;}
    public string TeamA_name {get; set;}
    public override int Group_id {get; set;}
    public virtual GroupA Group {get; set;}
}
```
